HTML & CSS

What is HTML?

HTML are just initials that mean **H**yper**T**ext **M**arkup **L**anguage. Keep in mind, People who are experts on computers love initials and acronyms.

Hyper - is the opposite of linear. Computers used to move in a linear fashion, which means that they do “this before this, this before this” and so on. HTML doesn't hold to that pattern and allows the person viewing the World Wide Web page to go anywhere, anytime they want.

Text - Is what you will use. Real, english letters.

Markup - Is what you will do. You will write in plain ENglish and then mark up what is written.

Language - Because it’s a language, even though the language is plain English.

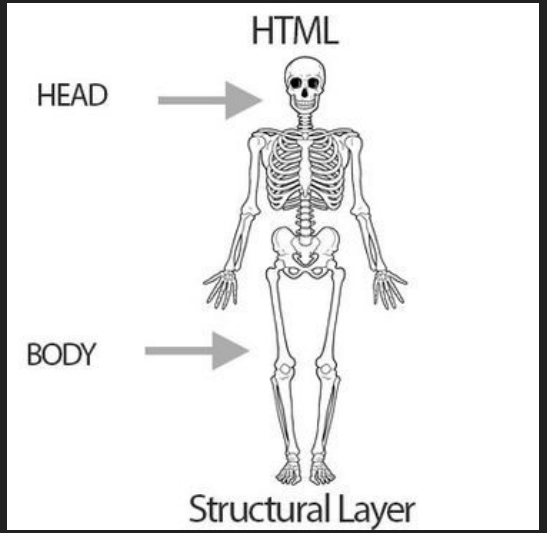

What does HTML do?

Basically, HTML is the basic structure and content of the website. A bit like the frames of a building or the skeleton of a human.

For example, if you find a website which is almost 100% HTML, you will notice that it isn't as refined and professional as the websites that you will find all the time, like amazon.com or even google.com.

The website works well, but overall the web page itself is not great looking. However, there is a way to improve the look of the website to make it look much more stylish and colourful. In the next slide, I will introduce to you what you can use to improve the looks of a website.

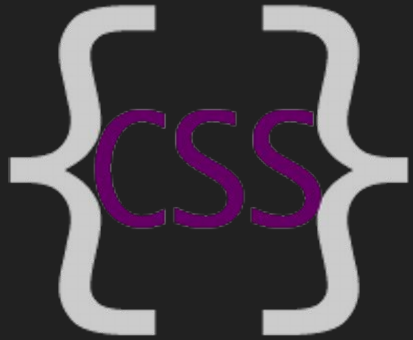

What is CSS?

CSS are just initials for **C**ascading **S**tyle **S**heets. As mentioned before, IT experts love initials and acronyms.

Cascading - means that styles can fall, or cascade, from one style sheet to another, enabling multiple style sheets to be used on one HTML document.

Style Sheet - is a file or form that makes the layout of a document. What I mean is that this can be used to change parts, or “parameters” of the website. Such as the page size, margins (the striped as around the edge of the paper) and the font (the look of the text used on the website).

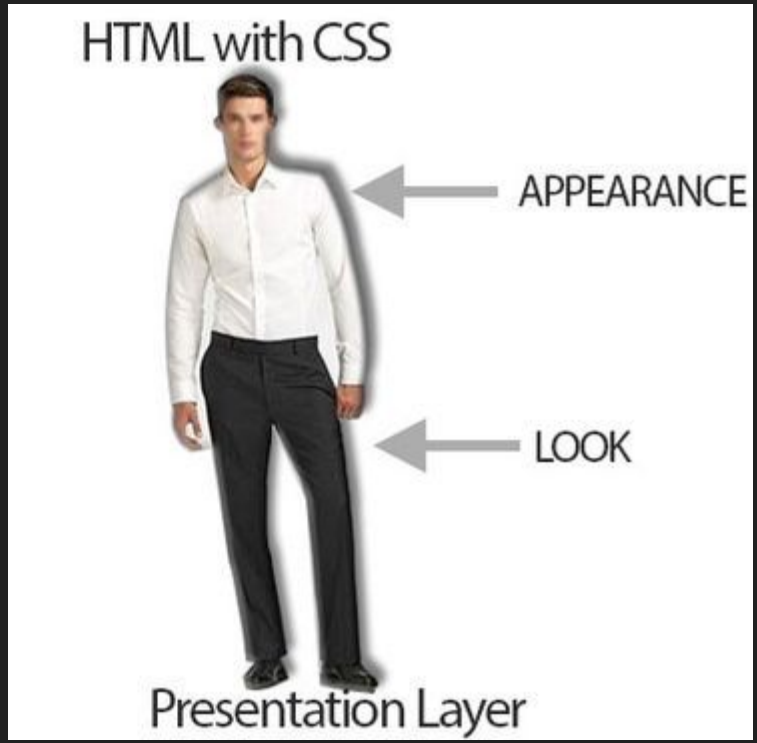

What does CSS do?

As I mentioned before, HTML is the building frames of a website. It works but doesn't look good. This is when CSS comes in.

CSS can be used to describe the looks of the website. Which includes colours, layout and fonts. It allows the creator to change the presentation to different types of electronic devices, like large screens, small screens or even printers.

As you probably noticed by now, CSS is completely independent from HTML, this makes it a lot easier to maintain websites, share style sheets across pages and tailor pages to different environments.

Examples of code

The code below is a very simple example of a portion from a HTML document, which show how to create a link within a paragraph. When shown on the screen, the link text will be “final report”. When someone activates the link, the browser will get the website which is called “http://www.example.com/report”:

```
<p class="moreinfo">For more information see the
<a href="http://www.example.com/report">final report</a>.</p>
```

The class attribute on the paragraph’s start tag (“<p>”) can be used, with a lot of other things, to add style. For example, to make the text on all the paragraphs italic (slanted slightly to the right), the creator would write in:

```
p.moreinfo { font-style: italic }
```

The creator can place that rule in a separate file, but it can be shared with the HTML document so it can still be used on the website

Thank you for your time
